
Rule 0.9 *⟨Avoid Explicit Zero Initialization⟩*

<pre> [...] contract A { [...] function f(pds) { [...] T var = defaultValue; stmts } [...] } </pre>	=	<pre> [...] contract A' { [...] function f(pds) { [...] T var; stmts } [...] } </pre>
--	---	--

where

var is a variable of type *T* being declared and initialized;

T is the type of the variable (e.g., **uint**, **bool**, **address**, etc.);

defaultValue is the default zero value for type *T* (e.g., 0 for **uint**, *false* for **bool**, **address(0)** for **address**);

stmts represents the sequence of statements following the declaration;

pds are the parameter declarations of function *f*.

provided

The explicit initialization value is exactly the default zero value for type *T*;

Solidity automatically initializes variables to their default zero values;

The variable *var* can be either a local variable or a state variable;

Removing the explicit initialization does not affect program semantics.

Invariant:

Let s_i and s'_i be the initial state of *A* and *A'*, respectively.

Let s_f and s'_f be the state reached by *A* and *A'*, respectively, after *A.f()* and *A'.f()* are executed from s_i and s'_i , respectively.

Then, the coupling invariant is

$$\forall s_i, s'_i . (s_i = s'_i) \rightarrow (s_f = s'_f)$$
